

10+0 Rapid Time Management Report

Chess.com account: loxi-ty | Last 50 games | 2026-03-09 to 2026-06-07 | Stockfish depth 8

Record 25-5-20 wins-draws-losses	Win rate 50% 25 wins from 50	Score 55.0% win=1, draw=0.5	Avg accuracy 85.9% fork report metric	Avg CP loss 36.7 per move, your side	Avg final clock 3:09 remaining at final move
---	---	--	--	---	---

Main finding

Slow and better beats fast and bad, but your best results come from fast and good. Fast+bad scored 32%; slow+better scored 63%; fast+good scored 96%.

Clock finding

Being up on time around move 15 scored 65% versus 47% when down. Finishing up on time scored 68% versus 42% when finishing down.

Danger zone

Moves 11-25 are where you spend the most time and where error frequency jumps. Long thinks above 40s had the highest mistake/blunder rate.

Practical target

Reach move 15 in about 2 minutes or less, reach move 25 with at least 3 minutes, and preserve at least 1-2 minutes for conversion or defence.

Method: Chess.com public archive data plus En Croissant fork analysis formula. The report is aggregate-only and does not annotate individual game moves.

Speed vs Quality

Fast/slow split: first 15 moves below/above 2:04. Good/bad split: game accuracy above/below 87.0%.

Score percentage by speed/quality bucket

Average analysed accuracy

Average final clock

Interpretation: the costly pattern is not speed itself. It is spending time without improving decision quality. Your mathematically best bucket was fast+good, but when accuracy drops, speed alone collapses results.

Clock Advantage Checkpoints

How results change when you are up or down on the clock after complete move numbers.

Checkpoint	Games	Avg diff	Up score	Down score
Move 10	50	0:04	58.0%	52.0%
Move 15	49	-0:10	64.7%	46.8%
Move 20	46	0:04	55.0%	48.1%

The move-15 split is the cleanest practical signal: up on time scored 64.7%; down on time scored 46.8%.

Endgame Clock Outcomes

Final clock and final clock-difference buckets. Small bins should be read as directional rather than absolute law.

Result by final clock remaining

Result by final clock difference

Final clock	n	W-D-L	Score	Avg clock
<30s	4	1-1-2	37.5%	0:10
30-60s	8	2-1-5	31.2%	0:50
60-120s	5	3-1-1	70.0%	1:41
120-240s	18	9-2-7	55.6%	2:52
≥240s	15	10-0-5	66.7%	6:00

Move-Time Quality

Per-move error statistics from the analysed positions, bucketed by how long you spent on the move.

Average CP loss by move time

Error rate by move time

Move range	Moves	Avg spent	Avg CP loss	Mistake/blunder
1-10	500	5.2s	12.9	1.2%
11-25	708	15.4s	37.4	6.5%
26+	815	8.7s	52.8	8.5%

Important: long-think moves are often hard positions, so this is not proof that thinking causes errors. But it is evidence that long thinks need a decision rule, not open-ended calculation.

Mathematical Improvement Rules

Rules derived from the aggregate stats, not from individual-game annotations.

1. Protect the move-15 clock

Target: be at least equal on time by move 15, preferably +30s. In this sample, being up on time at move 15 scored 64.7%; being down scored 46.8%.

2. Keep the opening budget tight

Your highest-scoring time bucket was first 15 moves under 2 minutes. Play known openings quickly unless the position has a forcing tactical branch.

3. Cap non-forcing long thinks

Moves over 40s had 61 average CP loss and a 14.8% mistake/blunder rate. If there is no concrete calculation after about 35-40s, choose a safe improving move.

4. Preserve a conversion reserve

Games ending under 60s scored about 33%; games with 4+ minutes left scored 67%. Aim to reach move 25 with at least 3 minutes and the final phase with at least 1-2 minutes.

5. Train the slow+bad positions

Slow+bad scored only 23%. Those are likely positions where extra time is being spent without a reliable candidate-move process. Review them by theme separately if you want the biggest lift.

Phase	Clock budget	Purpose
First 10 moves	~5 sec/move	Use prep and pattern recognition
Moves 11-25	10-15 sec average	Spend here, but cap non-forcing thinks
Move 25+	Keep 1-2+ min	Avoid losing winning/drawn positions on clock

Source: Chess.com Published Data API archives for public games. Analysis: local Stockfish depth 8 plus the En Croissant fork's game-report accuracy formula. Account assumption: loxi-ty was used because it is the local Chess.com account with enough recent 10+0 rapid games.
